## IMPROVEMENTS IN THE CONVERSION OF CHEMICAL MOIETIES

This invention relates to improvements in or relating to processes for converting fluidised chemical moieties.

In general, reactions need energy to initiate the reaction. Where this activation energy is high, the reaction is commonly carried out at high temperature and/or pressure. We have now found a new method of supplying the energy which enables reactions to be carried out at lower pressures, e.g. atmospheric pressure or sub-atmospheric pressure and/or lower temperatures. The reactions therefor, require less energy and are safer. The ability to carry out the reactions at lower temperatures and pressures also means that cheaper materials and simpler methods of construction can be used in the construction of the reaction vessels.

Alternatively improved results may be obtained at the higher temperature and/or pressure.

In accordance with the present invention, there is provided an improvement in processes for the conversion of a chemical moiety characterised in that the chemical moiety is in a fluid phase and said moiety is reacted with a plasma or with a reagent generated by the interaction of the plasma with another component. The process may involve the use of a catalyst.

It is to be understood that the term conversion, as used herein, relates to the conversion of a material to a desired product and not merely to surface modification. It is also to be understood that the invention relates to conversion of one chemical by treatment with a plasma which is not derived from the same molecule, and thus does not relate, for example, to plasma polymerisation.

**USES OF INFORMATION ONLY**

# IE CONVERSION OF CHEMICAL MOIETIES

is to improvements in or relating to ing fluidised chemical moieties.

need energy to initiate the reaction. n energy is high, the reaction is at high temperature and/or pressure. new method of supplying the energy ions to be carried out at lower spheric pressure or sub-atmospheric wer temperatures. The reactions s energy and are safer. The ability actions at lower temperatures and that cheaper materials and simpler n can be used in the construction of

d results may be obtained at the l/or pressure.

present invention, there is provided rocesses for the conversion of a iterised in that the chemical moiety and said moiety is reacted with a ent generated by the interaction of r component. The process may involve

d that the term conversion, as used he conversion of a material to a t merely to surface modification. It tood that the invention relates to ical by treatment with a plasma which he same molecule, and thus does not o plasma polymerisation.

The moiety may be an element or a compound and may be gaseous or liquid or it may be a solid which is in fluidised form. Where the chemical moiety is a liquid, e.g. through which the plasma is bubbled, it may be provided as such or as an aerosol, in which case the carrier gas may be or comprises the gas that is excited to plasma.

In the embodiment where the moiety is reacted with a reagent generated by the action of the plasma on another component, the plasma may be directed, for example, onto the surface of a solid to produce reactive species which react with the moiety. The solid may be a catalyst, for example. Alternatively, the reactive species may be generated from the action of the plasma on a liquid.

Plasma is normally generated from a gas; however, a liquid may also be used. For example, water may be excited to form plasmas of hydrogen and oxygen.

Any suitable means may be employed for generating the plasma. For example, it may be generated by DC glow discharge, AC electric field, plasma torch and heat, all of which may be pulsed. The heat may be generated by laser.

Alternating currents for generating the AC plasmas are preferably those having a frequency of  $1-10^4$ Hz, more preferably  $10^3-10^4$ Hz. It will be understood, however, that in some countries the frequencies that may be used are limited, e.g. because of the risk of interference with radio transmissions. For example, in Great Britain, a frequency of 13.56MHz is set aside by the Government for such experiments and will not therefore interfere with radio transmissions. Other frequencies can be used, provided that the Government is advised of the intention to use these frequencies.

Other frequencies can be used, arnment is advised of the intention to

Frequencies of less than 1 Hz may also be used. However, such frequencies may give rise to alternating or periodic glow discharge rather than a continuous plasma. Such discharges are advantageous when the power input has to be minimised or to provide additional control of the reaction.

Plasma that is generated by alternating current at radio-frequency is normally generated from gases at sub-atmospheric pressure. Pressures of from 100 to  $10^{-3}$  torr are suitable. However, the pressure used is dependent on the power loadings. Therefore, if a sufficiently high power loading is available, it is possible to excite gas to plasma at a pressure above 100 Torr, if desired.

However, plasmas generated by other means such as arc plasma or plasma torch are often generated at a variety of pressures ranging from sub- to super-atmospheric.

Where the reaction vessel is large, as in an industrial scale reaction, it is preferable to generate the plasma at lower frequencies such as 40kHz so as to reduce the likelihood of the plasma varying in intensity across the vessel. If higher frequencies are used, nodes and antinodes of plasma intensity may be created which may result in power loss and a reduction in the efficiency of the process.

A mixture of more than one plasma may be employed and where more than one gas or liquid is excited to plasma, this may be effected before or after mixing.

While the process of the invention may be applied to conversions generally, and more particularly gaseous reactions, it is particularly useful for converting toxic gases, such as are present in internal combustion engine exhaust gases and gaseous industrial emissions, to non-toxic waste products. Either or both of the toxic gas and

than 1 Hz may also be used. However, give rise to alternating or periodic or than a continuous plasma. Such ageous when the power input has to be be additional control of the reaction.

ted by alternating current at radio-ly generated from gases at sub-Pressures of from 100 to 10<sup>-3</sup> torr, the pressure used is dependent on Therefore, if a sufficiently high ble, it is possible to excite gas to above 100 Torr, if desired.

one plasma may be employed and where liquid is excited to plasma, this may after mixing.

f the invention may be applied to y, and more particularly gaseous icularly useful for converting toxic resent in internal combustion engine seous industrial emissions, to non- Either or both of the toxic gas and

the gas employed to convert it to a non-toxic product may be converted to plasma.

Internal combustion engine exhaust gases and other exhausts from hydrocarbon burning consist mainly of CO, NOx and gaseous hydrocarbons. The NOx can be detoxified by reaction with CO or unburned hydrocarbons to give N<sub>2</sub> and CO<sub>2</sub>. Excess carbon monoxide and unburned hydrocarbon fuel are normally oxidised to CO<sub>2</sub> and water.

Examples of the detoxification of industrial gaseous emissions include the denaturing of NOx to water and nitrogen gas using hydrogen plasma, the dehalogenation of organic molecules using hydrogen plasma and the removal of odour from industrial emissions such as the emissions from fat rendering, glue and size manufacturing, tanning, fish meal processing, polyvinyl chloride and polyurethane manufacturing and cutting, food manufacturing, coffee roasting, manure processing and meat processing industries. Some of these detoxification reactions may require the presence of a catalyst.

Exhaust gases and gaseous industrial emissions commonly include fine particulate matter dispersed in the gas. The process of the present invention may be used to convert the particular moieties to more acceptable gaseous products, to soluble products which can then be removed from the gas e.g. by washing, or to liquids which can be separated from the gas. For example, carbonaceous material such as soot can be treated with an oxygen plasma to form carbon dioxide.

Some reactions have such a high energy of activation that they have to be carried out at very high temperature and/or be initiated by free radicals even in the presence of a catalyst. We have now found that if such reactions are carried out in the presence of plasma in accordance with

such a high energy of activation that ed out at very high temperature and/or radicals even in the presence of a now found that if such reactions are resence of plasma in accordance with

this invention, the need for high temperature or free radical initiators may be reduced or obviated. Alternatively, the results achieved using such high temperature and/or free radical initiators may be improved. Reactions which may be carried out in this manner include, but are not limited to, hydrogenations such as of olefins, acetylenes, aldehydes, ketones, acids, anhydrides, esters, nitro compounds, nitriles, oximes, carboxylic aromatic compounds, anilines, phenols and derivatives thereof, reductive alkylation, reductive amination, dehalogenation, hydrogenolysis, isomerization, disproportionation migration, decomposition, carbonylation, decarbonylation, selective oxidation, acetoxylation and gas purification.

Whilst the present invention has particular advantages when used with reactions which have previously required high temperature and/or free radical initiation, it may also be used for reactions which do not have such a high activation energy.

Many reactions are promoted by catalysts that become deactivated with the passage of time. As described in our co-pending application, entitled "Improvements in Processes Involving Catalyst", filed on the same day as the present application, such catalyst may be regenerated by contacting the surface of the catalyst with a gas in the form of a plasma. Processes may therefore be envisaged in which both the reactant mixture for a catalysed gaseous reaction and the catalyst regeneration employ plasma.

In accordance with one aspect of such processes, the catalysed reaction may take place in one time period and the regeneration of the catalyst in a second, subsequent period. Two reactors may be employed in parallel, in one of which the reaction is taking place and in the other of which the regeneration is taking place. When the catalyst in the second reactor has been regenerated, the operations

need for high temperature or free may be reduced or obviated. results achieved using such high radical initiators may be improved. carried out in this manner include, hydrogenations such as of olefins, ketones, acids, anhydrides, esters, aldes, oximes, carboxylic aromatic phenols and derivatives thereof, reductive amination, dehalogenation, isomerization, disproportionation, on, carbonylation, decarbonylation, detoxylation and gas purification.

tion has particular advantages when which have previously required high radical initiation, it may also be. h do not have such a high activation

promoted by catalysts that become ssage of time. As described in our entitled "Improvements in Processes lled on the same day as the present yst may be regenerated by contacting catalyst with a gas in the form of a therefore be envisaged in which both or a catalysed gaseous reaction and on employ plasma.

ie aspect of such processes, the take place in one time period and e catalyst in a second, subsequent ay be employed in parallel, in one is taking place and in the other of is taking place. When the catalyst as been regenerated, the operations

in the two reactors may be reversed so that the reaction is effected over regenerated catalyst in the second reactor while the catalyst of the first reactor is regenerated. Of course, more than two reactors may be used with appropriate switching arrangements.

In some cases, the gas or gases required to regenerate the catalyst may already be included in, or readily generated from, the gaseous mixture which is to be treated in the presence of the catalyst. In such cases, a self-contained procedure can be envisaged where in one step the gaseous mixture is treated to convert to plasma the gaseous component, or at least one of the gaseous components, employed in the regeneration of the catalyst and in another step the same mixture is treated to convert to plasma at least one of the other gases of the mixture, being a gas involved in the reaction which is promoted by the catalyst. The first step may also involve a reaction to generate a required gas, e.g. the gas which is to be converted to plasma, where it is not already present as such in the reaction mixture.

An example of such a case is the detoxification of exhaust gas emissions from motor vehicles. For example, the catalyst employed in the catalytic converters fitted to motor vehicles for the detoxification of the exhaust gases tend to be deactivated with time due to poisoning by lead and/or phosphorus which are employed in additives for motor fuels.

Lead can be removed from the surface of the catalyst by the action of chlorine plasma which converts it to a soluble salt and phosphorus can be removed by the action of hydrogen plasma; the reactions proceeding according to the following equations:

may be reversed so that the reaction is reversed catalyst in the second reactor; the first reactor is regenerated. Of course, reactors may be used with appropriate catalysts.

As for gases required to regenerate the catalyst, be included in, or readily generated in the mixture which is to be treated in the catalyst. In such cases, a self-contained catalyst where in one step the gaseous mixture is converted to plasma the gaseous mixture, at least one of the gaseous components, regeneration of the catalyst and in another step the catalyst is treated to plasma at least one of the gaseous components, the mixture, being a gas which is promoted by the catalyst. Also involve a reaction to generate a gas which is to be converted to plasma not already present as such in the

case is the detoxification of exhaust motor vehicles. For example, the catalytic converters fitted to the exhaust of the exhaust gases are detoxified with time due to poisoning by lead and are employed in additives for motor

from the surface of the catalyst by the plasma which converts it to a soluble form which can be removed by the action of reactions proceeding according to the

---> 2Cl (chlorine plasma)

Thus, where halogenated compounds, for example  $\text{CCl}_4$  and  $\text{H}_2$ , are present in the exhaust gases or can be generated from a gas or gases present in these gases, it will be appreciated that the regeneration of the catalyst may be achieved using the exhaust gas itself by treating it to convert one or both of the chlorine and hydrogen components thereof to plasma.

Catalytic converter systems for motor vehicles can therefore be designed wherein the catalyst is regenerated on board the vehicle, using the vehicle engine's exhaust emissions.

Where the plasma or plasmas employed for the catalyst regeneration do not interfere with the reaction which is being promoted by the catalyst, it may even be possible to effect the catalysed reaction and the regeneration of the catalyst simultaneously.

An example of an application of the present invention to an important industrial process is in the Haber process for the catalytically promoted synthesis of ammonia from nitrogen and hydrogen. The catalyst is usually trivalent iron. Known methods require that the reaction is carried out at high temperatures and pressures such as 670K and 150 to 350 atm. Where the reaction is carried out according to the present invention, lower temperatures and pressures can be used thus reducing the risk of explosion, the energy required to carry out the synthesis and its cost.

In practice, a stoichiometric mixture of nitrogen and hydrogen is excited to plasma by any means in the presence

-----> PbCl<sub>2</sub>

-----> PbCl<sub>4</sub>

-> 2H (hydrogen plasma)

-----> PH<sub>3</sub>

compounds, for example CCl<sub>4</sub> and H<sub>2</sub>, must gases or can be generated from nit in these gases, it will be regeneration of the catalyst may be must gas itself by treating it to the chlorine and hydrogen components

systems for motor vehicles can herein the catalyst is regenerated using the vehicle engine's exhaust

lasmas employed for the catalyst interfere with the reaction which is catalyst, it may even be possible to action and the regeneration of the

tion of the present invention to an cess is in the Haber process for noted synthesis of ammonia from The catalyst is usually trivalent quire that the reaction is carried and pressures such as 670K and 150 action is carried out according to lower temperatures and pressures can the risk of explosion, the energy e synthesis and its cost.

ometric mixture of nitrogen and lasma by any means in the presence

of the catalyst to produce the ammonia. Alternatively, the admixture of hydrogen and nitrogen is excited prior to being passed over the catalyst. In this case, the catalyst will be located in a separate zone to that in which the gases are excited to plasma. The plasma is then brought into contact with the catalyst at the desired temperature and pressure. If desired, one only of the hydrogen and nitrogen is converted to plasma.

The cleavage of a carbon-carbon double bond by oxidation with ozone followed by hydrolysis to yield carbonyl compounds is an example of an application of the present invention where the moiety to be converted is a liquid. A plasma of oxygen is bubbled through a solution of the unsaturated organic compound in an inert solvent such as methanol, glacial acetic acid, ethyl acetate, hexane or chloroform at a temperature which is preferably in the region of -20°C but which may be at or above ambient temperature. The ozone is produced in the oxygen plasma.

The plasma may convert the chemical moiety to a reactive substance which then takes part in a further reaction. For example, aluminium hydride may be mixed with a catalyst poisoned with sulphur and phosphorus. The mixture is exposed to a plasma of an inert gas to decompose the aluminium hydride to aluminium and hydrogen species. These species then react with the sulphur and phosphorus poisons to form a mixture of products, namely aluminium sulphide, aluminium phosphide, hydrogen sulphide and phosphine.

Alternatively, the catalyst may be mixed with zinc oxide and exposed to a hydrogen plasma. Both reactive poisons, such as mercaptan and thiol compounds, and unreactive poisons, such as aromatic sulphur compounds can be removed from the catalyst surface by this means.

An example of the chemical moiety being converted to a

duce the ammonia. Alternatively, the hydrogen and nitrogen is excited prior to the catalyst. In this case, the catalyst is separated from the plasma zone in which the plasma is then brought to the desired temperature, one only of the hydrogen and nitrogen is brought to plasma.

Carbon-carbon double bond by oxidation by hydrolysis to yield carbonyl compounds. An application of the present invention to be converted is a liquid. A solution of the compound in an inert solvent such as acetic acid, ethyl acetate, hexane or heptane which is preferably in the liquid phase may be at or above ambient temperature and is produced in the oxygen plasma.

The chemical moiety to a reactive moiety takes part in a further reaction. For example, a thiol may be mixed with a catalyst and phosphorus. The mixture is then of an inert gas to decompose the thiol and hydrogen species. These products, namely aluminium sulphide, hydrogen sulphide and phosphine.

The catalyst may be mixed with zinc oxide and hydrogen plasma. Both reactive poisons, and thiol compounds, and unreactive thiol sulphur compounds can be removed from the surface by this means.

The chemical moiety being converted to a

reactive substance where the moiety is a liquid is where a catalyst poisoned with hydrocarbons and lead is suspended in or is in contact with dichlorine heptoxide. When the mixture is exposed to plasma of oxygen and/or inert gas, the oxygen and chlorine species formed will respectively oxidise the hydrocarbons and convert the lead to a washable lead salt.

5, wherein the emission or exhaust is a fluidised

5, wherein the emission or exhaust is in gaseous m of plasma.

19. A process according to any one of Claims 15 to 19, wherein the plasma is generated by an AC electric field, by DC glow discharge, by a laser or by plasma torch.

20. A process according to Claim 19, wherein the plasma is generated by an AC electric field and wherein the alternating current is supplied at from  $10^3\text{Hz}$  to  $10^9\text{Hz}$ .

21. A process according to Claim 19, wherein the plasma is generated by an AC electric field and wherein the alternating current is supplied at from  $10^3\text{Hz}$  to  $10^{12}\text{Hz}$ .

22. A process according to any one of Claims 15 to 21, wherein said another component is a solid.

23. A process according to Claim 22, wherein said another component is the catalyst.

24. A process according to any one of Claims 15 to 23, wherein the reaction of the emission or exhaust with the plasma generates a reactive species which takes part in a second reaction.

25. A process according to any one of Claims 15 to 24, wherein the conversion is carried out as a continuous, semi-continuous or batch process.

any one of Claims 15 to 19, wherein the plasma is field, by DC glow discharge, by a laser or by plasma

Claim 19, wherein the plasma is generated by an AC alternating current is supplied at from  $10^3$ Hz to  $10^6$ Hz.

Claim 19, wherein the plasma is generated by an AC alternating current is supplied at from  $10^3$ Hz to  $10^2$ Hz.

any one of Claims 15 to 21, wherein said another

claim 22, wherein said another component is the catalyst.

any one of Claims 15 to 23, wherein the reaction of the plasma generates a reactive species which takes part in

o any one of Claims 15 to 24, wherein the conversion is semi-continuous or batch process.

## INTERNATIONAL SEARCH REPORT

PCT/GB 93/01641

International Application No.

According to International Patent Classification (IPC) and to both National Classification and IPC

IPC: B 01 D 53/00, B 01 D 53/32, B 01 D 53/34, B 01 D 53/36,  
B 01 J 19/08, H 05 H 1/24, C 10 G 15/12

## II. FIELDS SEARCHED

<sup>1</sup> Special categories of cited documents: "A" document defining the general state of the art which is not considered to be of particular relevance  
"E" earlier document but published on or after the international filing date  
"L" document which may throw doubt on priority claim(s) or which it refers to in order to establish the priority claim(s)  
"O" document referring to an oral disclosure, use, exhibition or other means  
"P" document published prior to the international filing date but later than the priority date claimed

<sup>2</sup> Later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention  
"X" document of particular relevance: the claimed invention cannot be considered novel or cannot be considered to involve an inventive step in view of the prior art  
"Y" document of particular relevance: the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, each combination being obvious to a person skilled in the art  
"Z" document member of the same patent family
